Restorative Treatment

Fillings are placed after decay is removed to then restore the tooth back to a healthy state.

Crowns are often needed following a root canal to strengthen the tooth. They are also needed if a tooth has a large crack or extensive decay.

Bridges are a non-removable prosthetic that bridges the gap between remaining teeth.

Partial dentures are a removable appliance that replaces missing teeth and surrounding tissue. They often contain metal framework.

Complete conventional dentures are a removable appliance that replaced missing teeth and surrounding tissue. These are made when replacing lost dentures, old dentures or after there has been some initial healing of the gum and bone tissue following extractions.

Immediate Dentures are a removable appliance that replaces missing teeth and surrounding tissue. These are made to be place immediately following the extractions of the teeth. This method is often used so that the patient has teeth right away.

Root Canals are need when decay has entered into the nerve or there is an infection within the tooth. The nerve is removed from the tooth and replaced with a root canal filling material.
